

Loop

Session 6

Objectives

- Understand 'for' loop in 'C'
- Work with comma operator
- Understand nested loops
- Understand the 'while' loop and the 'do-while' loop
- Work with break and continue statements
- Understand the exit() function

What is a Loop?

**Section of code in a program
which is executed repeatedly,
until a specific condition is satisfied**

3 types of Loop Structures

The for loop

The while loop

The do....while loop

The **for** loop-1

Syntax

```
for (initialize counter; conditional test; re-evaluation parameter)
{
    statement
}
```

- The initialize counter is an assignment statement that sets the loop control variable, before entering the loop
- The conditional test is a relational expression, which determines, when the loop will exit
- The evaluation parameter defines how the loop control variable changes, each time the loop is executed

The **for** loop-2

- The three sections of the **for** loop must be separated by a semicolon(;)
- The statement, which forms the body of the loop, can either be a single statement or a compound statement
- The **for** loop continues to execute as long as the conditional test evaluates to true. When the condition becomes false, the program resumes on the statement following the **for** loop

The **for** loop-3

```
/*This program demonstrates the for loop in a C program */  
#include <stdio.h>
```

```
main()  
{
```

```
    int count;  
    printf("\tThis is a \n");
```

```
    for(count = 1; count <=6 ; count++)  
        printf("\n\t\t nice");
```

```
    printf("\n\t\t world. \n");
```

```
}
```

Example

The Comma Operator

The scope of the **for** loop can be extended by including more than one initializations or increment expressions in the for loop specification

The format is : **exprn1 , exprn2 ;**

```
#include <stdio.h>
```

```
main()
```

```
{
```

```
    int i, j , max;
```

```
    printf("Please enter the maximum value \n");
```

```
    printf("for which a table can be printed: ");
```

```
    scanf("%d", &max);
```

```
    for(i = 0 , j = max ; i <=max ; i++, j--)
```

```
        printf("\n%d + %d = %d", i, j, i + j);
```

```
}
```

Example

Nested **for** Loops-1

The **for** loop will be termed as a **nested for** loop when it is written as follows

```
for(i = 1; i<max1; i++)  
{  
    .  
    .  
    for(j = 0; j <= max2; j++)  
    {  
        .  
        .  
    }  
    .  
    .  
}
```

Nested **for** Loops-2

```
#include <stdio.h>
```

```
main()
```

```
{
```

```
    int i, j, k;
```

```
    i = 0;
```

```
    printf("Enter no. of rows :");
```

```
    scanf("%d", &i);
```

```
    printf("\n");
```

```
    for (j = 0; j < i ; j++)
```

```
    {
```

```
        printf("\n");
```

```
        for (k = 0; k <= j; k++) /*inner for loop*/
```

```
        printf("*");
```

```
    }
```

```
}
```

Example

The **while** Loop-1

Syntax

```
while (condition is true)  
    statement ;
```

The while loop repeats statements while a certain specified condition is True

The **while** Loop-2

`/* A simple program using the while loop */`

```
#include <stdio.h>
```

```
main()
```

```
{
```

```
    int count = 1;
```

```
    while( count <= 10)
```

```
{
```

```
        printf("\n This is iteration %d\n",count);  
        count++;
```

```
}
```

```
printf("\n The loop is completed. \n");
```

```
}
```

Example

do...while Loop-1

Syntax

```
do{  
    statement;  
} while (condition);
```

- In the **do while** loop the body of the code is executed once before the test is performed
- When the condition becomes False in a **do while** the loop will be terminated, and the control goes to the statement that appears immediately after the **while** statement

do...while Loop-2

Example

```
#include <stdio.h>
main ()
{
    int num1, num2;
        num2 = 0;

    do
    {
        printf( "\nEnter a number : " );
        scanf( "%d", &num1 );
        printf( " No. is %d", num1 );
        num2++;
    } while (num1 != 0);
    printf ( "\nThe total numbers entered were %d", --num2 );

    /*num2 is decremented before printing because count for last
    integer (0) is not to be considered */
}
```

Jump Statements-1

`return` expression

- The return statement is used to return from a function
- It causes execution to return to the point at which the call to the function was made
- The return statement can have a value with it, which it returns to the program

Jump Statements-2

`goto label`

- The goto statement transfers control to any other statement within the same function in a C program
- It actually violates the rules of a strictly structured programming language
- They reduce program reliability and make program difficult to maintain

Jump Statements-3

break statement

- The break statement is used to terminate a case in a switch statement
- It can also be used for abrupt termination of a loop
- When the break statement is encountered in a loop, the loop is terminated immediately and control is passed to the statement following the loop

break statement

Example

```
#include <stdio.h>
main ()
{
    int count1, count2;
    for(count1 = 1, count2 = 0; count1 <=100; count1++)
    {
        printf("Enter %d count2 : ", count1);
        scanf("%d", &count2);
        if(j==100) break;
    }
}
```

Jump Statements-4

continue statement

- The continue statement causes the next iteration of the enclosing loop to begin
- When this statement is encountered, the remaining statements in the body of the loop are skipped and the control is passed on to the re-initialization step

continue statement

```
#include <stdio.h>
main ()
{
    int num;
    for(num = 1; num <=100; num++)
    {
        if(num % 9 == 0)
            continue;
        printf("%d\t", num) ;
    }
}
```

Example

Jump Statements-5

`exit()` function

- The `exit()` is used to break out of the program
- The use of this function causes immediate termination of the program and control rests in the hands of the operating system
